## Online Supplement to Point and interval estimates for a standardized mean

difference in paired-sample designs using a pooled standard deviation by Douglas A. Fitts

Table S1. Calculated sample sizes for a $90 \%$ paired-pooled confidence interval (CI) having an average fixed full width of $\omega$ in standard deviation units. The sample size $n$ assumes a noncentral $t$ distribution with known population correlation $\rho$. Simulations with these parameters for $90 \%$ using the Pearson correlation $r$ instead of $\rho$ required about 1 extra subject. $\delta$ is the population standardized effect size.

|  | $\omega$ |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Documentation of the variability of the simulations with identical parameters.

Figure 9 illustrates the variability in coverage produced by 10 independent identical runs of 50,000 iterations. These were $95 \%$ paired-pooled noncentral $t$ CIs using independent samples from $n=10$ through 100 . The mean $M_{M}$ and standard deviation $S_{M}$ of the 10 means were used to construct two-tailed $95 \%$ central $t$ CIs $\left(M_{M} \pm\left(S_{M}\right)\left(t_{v=9}\right)\right)$ at each $n$ for the observed CI (top and middle) and the fixed-width CI (bottom) at $\omega$ values of 0.4 and 0.8 with $\delta=0.4$ and $\rho=.4$. The protocol $[\omega=0.8 ; \delta=0.4 ; \rho=.4]$ in green is a multiple replication of the simulation plotted in Figure 3, row 3 , for $\rho=.4$. The mean of the means is therefore based on 500,000 experiments. The scaling on the ordinate is the same as in Figure 3 (the bottom panel is stretched vertically with the same scaling to accommodate the new data for $\omega=0.4$ ).

Most of the means from Figure 3, row 3 for $\delta=0.4$ on the left for the observed CI, fall within these limits in Figure 9. These results cannot rule out differences according to $\delta$ and $\rho$ with the observed CI, but if such differences exist (Cousineau \& Goulet-Pelletier, 2021, Figure B7), they are small and within the bounds of normal variability of the present method. For example, I reran the simulations $[\omega=0.8 ; \delta=0.4 ; \rho=.0, .2, .4, .6$, and .8$]$ and $[\omega=0.8 ; \delta=0.0$, $0.2,0.4,0.6,0.8,1.0 ; \rho=.4]$ with $1,000,000$ iterations to discover potential differences in the coverage of the observed CI attributable to $\rho$ or $\delta$ with these specific parameters. With these tests at these parameters, the maximum difference in coverage of the observed CI between any two values of $\rho$ was 0.0015 and the maximum difference between any two values of $\delta$ was 0.0013 . Both are within the normal variability of the method with 50,000 iterations according to Figure 9.

This fixed-CI method was used to identify sample sizes for CIs in Tables S1 to S3. If we look up the recommended $n$ for Figure $9[\omega=0.8 ; \delta=0.4 ; \rho=.4]$ in Table S2, the calculated
value was 30 and the value for using $r$ instead of $\rho$ was $30+2=32$. In the independent simulations in Figure 9, the mean sample size determined from the 10 simulations for these parameters was 31 in 3 of 10 and 32 in 7 of 10 simulations for an average of $n=31.7$. These sample size estimations are highly stable.

Figure 9. Illustration of the variability of independent samples with identical parameters and 50,000 iterations. Means and $95 \%$ central $t$ CIs of coverages of 10 independent simulations of $95 \%$ paired-pooled noncentral $t$ CIs with identical $\delta$ and $\rho$ parameters with sample sizes varying from 10 to 100 with $\omega$ either 0.4 (dark red) or 0.8 (green). Compare to Figure 3 at the same scale.
